1. let $g(x) = f(x) - \frac{\mu}{2} \|x\|^2$, $g(x)$ is convex, then

$$\begin{cases} g(y) \geq g(x) + [\nabla g(x)]^T (y-x) \\ g(x) \geq g(y) + [\nabla g(y)]^T (x-y) \end{cases}$$

$$\Leftrightarrow \begin{cases} f(y) - f(x) \geq \frac{\mu}{2} (\|y\|^2 - \|x\|^2) + [\nabla f(x)]^T (y-x) - \mu x^T y + \mu \|x\|^2 & \textcircled{1} \\ f(x) - f(y) \geq \frac{\mu}{2} (\|x\|^2 - \|y\|^2) + [\nabla f(y)]^T (x-y) - \mu y^T x + \mu \|y\|^2 & \textcircled{2} \end{cases}$$

by $\textcircled{1} + \textcircled{2}$, we have $[\nabla f(x) - \nabla f(y)]^T (x-y) \geq \mu (\|x\|^2 + \|y\|^2 - x^T y - y^T x) = \mu \|x-y\|^2$.

Thus, the inequality holds. $\forall x, y \in \mathbb{R}^n$. \square .

2. (a) $\begin{cases} x_1 - x_2 - x_3 \leq 1 \\ x_2 - x_4 \leq 2 \\ x \geq 0 \end{cases} \Rightarrow \begin{cases} x_1 \leq 1 + x_2 + x_3 \leq 3 + x_3 + x_4 \\ x_2 \leq 2 + x_4 \\ x_{1,2,3,4} \geq 0 \end{cases}$

So the boundary points are $(3+x_3+x_4, 2+x_4, x_3, x_4)$. $\forall x_3, x_4 \geq 0$.

the extreme/corner point is $(3, 2, 0, 0)$.

$\bar{x} = (3, 2, 0, 0)$ is extreme point because $\bar{A} \bar{x} = \bar{b}$, where $\bar{b} = \begin{bmatrix} 1 \\ 2 \\ 0 \\ 0 \end{bmatrix}$.

$\bar{A} = \begin{bmatrix} 1 & -1 & -1 & 0 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ is full-ranked, i.e. there are 4 linearly independent vectors at \bar{x} . \therefore it's a extreme point.

(b) the Linear Relaxation of the problem is

(LR) $\begin{cases} \max C^T x \\ \text{s.t. } Ax \leq b \\ x \geq 0 \end{cases}$, where $C^T = (1, 2, 3, -4)$, $A = \begin{bmatrix} 1 & -1 & -1 & 0 \\ 0 & 1 & 0 & -1 \end{bmatrix}$, $b = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$.

the dual of (LR) is: (D) $\begin{cases} \min b^T y \\ \text{s.t. } A^T y \geq c \\ y \geq 0 \end{cases}$ i.e. $\begin{cases} \min y_1 + 2y_2 \\ \text{s.t. } \begin{cases} y_1 \geq 1 \\ y_2 \geq 2 + y_1 \\ y_3 \leq 3 \\ y_4 \leq 4 \end{cases} \end{cases}$

the optimal solution of (D) is

$\bar{y} = (1, 3)$, $v_D^* = 7$

by duality theorem $\max C^T \bar{x} \leq \min b^T \bar{y} = 7$ $\textcircled{1}$

observe that $\bar{x} = (3, 2, 0, 0)$ is feasible for (LR) as (a) discussed.

and the solution is integer.

Moreover, $C^T \bar{x} = 7$ satisfies $\textcircled{1}$ and is optimal.

\therefore an optimal solution is $\bar{x} = (3, 2, 0, 0)$, optimal value is 7. \square

3.

(a) by definition, $F^*(y) = \sup_{u \in \mathbb{R}} \{uy - F(u)\} \geq xy - F(x), \forall x, y \in \mathbb{R}.$

$$\Rightarrow xy \leq F(x) + F^*(y), \quad \forall x, y \in \mathbb{R}.$$

(b) ~~$f(0)=0, f(x)$ is increasing $\therefore f(x) \geq 0, \forall x \geq 0; f(x) < 0, \forall x < 0.$~~ ✓let $b = f(a)$, then $g(b) = a$. $b=0$, then $a=0$, as f is \uparrow and $f(0)=0, b=y, a=g(y)$

$$\begin{aligned} G(y) &= \int_0^y g(b) db = \int_0^{g(y)} a df(a), \\ &= a f(a) \Big|_0^{g(y)} - \int_0^{g(y)} f(a) da \\ &= xy - F(x), \quad \text{where } g(y) \triangleq x. \quad (*) \end{aligned}$$

note that $xy \leq F(x) + F^*(y)$ as (a) proved. ①and $g = f^{-1}$, f is increasing, $\therefore \forall z, F(z) \geq F(x) + y(z-x), y \in \partial f$

$$\Leftrightarrow yx - F(x) \geq yz - F(z) \Leftrightarrow yx - F(x) \geq F^*(y). \quad \textcircled{2}$$

by ①, ②, $xy - F(x) = F^*(y)$ so, $G(y) = F^*(y)$. \square 6. ~~$\forall x \in \mathbb{R}^n, z \in C = \{x \in \mathbb{R}^n : x^T e \geq 0\}$. let $z^* = \Pi_C(x) \in C$ be projection of x onto C .~~~~then $\forall z \in C, (z - z^*)^T (x - z^*) \leq 0$.~~~~if $x^T e \geq 0$, i.e. $x \in C$, then $z^* = x$.~~~~if $x^T e < 0$,~~6. Note that $C = \{x \in \mathbb{R}^n : e^T x \geq 0\}$ is a half-space with hyperplane $H(e, 0) = \{x : e^T x = 0\}$ $\forall x \in \mathbb{R}^n$, if $x^T e > 0$, i.e. $x \in \text{int}(C)$, then the projection is x itself. ①if $x^T e \leq 0$, then the projection is on the hyperplane $H(e, 0)$,

$$\text{denoted as } z^*, \quad z^* \in H(e, 0) \Rightarrow e^T z^* = 0 \quad \textcircled{2}$$

$$(x - z^*) \perp H(e, 0) \Rightarrow e^T (x - z^*) = \alpha e \quad \textcircled{3}$$

$$\text{combine } \textcircled{2} \textcircled{3}, \quad e^T (x - \alpha e) = 0 \Rightarrow \alpha = \frac{1}{n} x^T e$$

$$\therefore z^* = x - \alpha e = x - \frac{1}{n} (x^T e) e \quad \textcircled{4}$$

with ①④, we have the projection

$$z^*(x) = \begin{cases} x, & \text{if } x^T e > 0 \\ x - \frac{1}{n} (x^T e) e, & \text{if } x^T e \leq 0. \end{cases}$$

which is the same as $P(x)$. \square

7. (a)

(a). $f(x)$ is convex. $\therefore \forall x \in \mathbb{R}^n$, $f(x) \geq f(\bar{x}) + [\partial f(\bar{x})]^T (x - \bar{x})$
 $\because 0 \in \partial f(\bar{x})$ for \bar{x} , $\therefore \forall x$, $f(x) \geq f(\bar{x}) + 0^T (x - \bar{x}) = f(\bar{x})$.
 $\therefore f(\bar{x}) = \min_{x \in \mathbb{R}^n} f(x)$, \bar{x} is a global optimal solution. \square

(b) Let $f(x) = \frac{1}{2} \|x - y\|_2^2 + \lambda \|x\|_1$, f is convex, non-differentiable.

$$\partial f(x) = \begin{cases} x - y + \lambda e, & x > 0 \\ x - y, & x = 0 \\ x - y - \lambda e, & x < 0 \end{cases}$$

as (a) discussed, let $\partial f(\bar{x}) = 0$, then $\bar{x} = \begin{cases} y - \lambda e, & \text{if } y > \lambda e \\ y, & \text{if } y = 0 \\ y + \lambda e, & \text{if } y < -\lambda e. \end{cases}$

is optimal for $\min_{x \in \mathbb{R}^n} \left\{ \frac{1}{2} \|x - y\|_2^2 + \lambda \|x\|_1 \right\}$. \square
